Abstract

In this report we present a compilation of the available information about plants common to Wisconsin lakes. Most aquatic plants have not been intensively studied; however, this report forms a basis for continued addition and refinement of the available data. The information presented includes scientific and common names, life form, species status, life cycle, propagation methods, wildlife and environmental values, potential nuisances, habitat preferences, and susceptibility to common aquatic herbicides.

Introduction

Producing stable, diverse aquatic plant communities containing high percentages of desirable species is a primary management goal from an economic and environmental perspective. To achieve this goal, a manager has to know which species are desirable and how to encourage them as well as which species are likely to be nuisances and how to discourage them.

Each species differs in its usefulness, susceptibility to management techniques, and habitat requirements. The cornerstone for successful plant management is a thorough knowledge of individual plant attributes. Is the species likely to be a nuisance? Can it be controlled with herbicides or drawdown? Can it be propagated from seed, cuttings, or rootstock? Will it grow in soft bottoms or turbid water? Is it valuable for fish or wildlife food? Will it help reduce erosion or stabilize bottom sediment? Does it have an aesthetically pleasing form or flower? These questions often need to be answered before designing an effective aquatic plant management plan.

Attribute tables

Information is presented in tabular form. The five tables list the plants, their habitat preference, wildlife and environmental value, propagation method, and herbicide susceptibility. The sources used in compiling the tables are cited at the end of each table. Except for table 1, the tables list only those plants for which attribute information is known. In cases where information is available only at the generic level, individual species in a genus are not listed.

Table 1 is a list of 149 taxa (developed by Nichols and Martin, 1990) of plants that are likely to be found in Wisconsin lakes. Included in table 1 are the scientific and common names of the plant; life form (submergent, emergent, floating leaf, or free floating); species status (abundant to rare, endangered, or non-native); and species code (used for computer retrieval of data).

Species status indicates how frequently each plant was found by Nichols and Martin (1990). An *abundant* (A) species was found in 35 percent of the lakes surveyed, *common* (C) species in 15 to 35

percent of the lakes, *infrequent* (I) species in 2 to 14 percent of the lakes and *rare* (R) species in less than 2 percent of the lakes.

Species status also indicates whether the Wisconsin Department of Natural Resources considers the species endangered (Wisconsin Department of Natural Resources, n.d.) and in need of special protection or whether the species is non-native. Many of the worst aquatic nuisances are exotic species.

Table 2 is a list, by species, of substrate preference, turbidity tolerance, and response to summer and winter drawdown. Where there have been conflicting opinions between authors about habitat preference, especially about turbidity association, more than one response may be listed. Information about substrate preference and turbidity tolerance is helpful for aquatic plant restoration; information about drawdown can be used to increase or decrease plant density.

Table 3 provides a qualitative assessment of environmental value so that decisions whether to encourage or discourage a species can become part of lake planning. Some plants have environmental value as food and cover for fish and wildlife and as a substrate stabilizer; other plants are potential nuisances.

In table 3 the food value of lake plants to waterfowl, other birds, and muskrats is rated if they directly use the plant for food; the value as food to fish includes direct use (which is generally limited) and indirect use (the value as food to invertebrates or other organisms that fish in turn use for food).

The value as cover is listed if fish are known to use the plant for cover. However, fish probably relate more to the structure of the plant community rather than to an individual species. For instance, one pondweed community is probably as valuable as another for fish cover if the structure of the two communities is the same, regardless of which specific pondweed species they contain. Although waterfowl and other birds use aquatic invertebrates for food during part of their life cycle, the value of plants as invertebrate habitat is not captured in this table.

The value for substrate stabilization is based partly on life form. Strongly rooted emergent species reduce shoreline erosion.

Aquatic plants have the ability to have an impact upon nutrient recycling in a lake. This environmental value is not reported in table 3 because it is partly related to the biomass of plants present. However, some species recycle nutrients more quickly than others. Not enough is known about the various species at this time to rate their nutrient recycling abilities.

Any species with overabundant growth has the potential to become a local nuisance. The species that cause at least local problems in the northeastern United States are indicated as potential nuisance species. Those that are documented as being aggressive nuisances in Wisconsin are much more limited in number.

Table 4 provides information that is valuable for revegetation. Where more than one propagation method is available, the technique selected will likely be based on the amount of area to be revegetated, budget, and the time needed to produce a stand of plants. Seed, for example, can be planted quickly over large areas, but it takes a longer time to establish plants than does planting transplants. Given enough time, equipment, and money, most species can be transplanted, but this may not be practical in many situations.

Table 5 provides general information about herbicide susceptibility. Question marks indicate that results are highly dependent upon specific chemical formulation or environmental conditions. Therefore, more skill in application may be needed for successful treatment of some plants than for others. With careful

planning, it may be possible to use herbicides selectively to change the species composition of established communities from less desirable to more desirable species.

Summary sheets

All known attribute information is available in summary sheets for the 117 individual taxa found in tables 2 through 5 (Nichols and Vennie, 1991). This format is useful for preparing lake reports: the attributes and management potential of a limited number of species can be quickly assessed by assembling the appropriate summary sheets.

See Appendix A for a list of the taxa included in the summary sheets, a sample summary sheet, and ordering information.

Data retrieval

The tables presented in this report and the summary sheets are available in computer-retrievable files from the Lake Management Program Office (attn: James Vennie), Wisconsin Department of Natural Resources, Box 7921, WR/2, Madison, Wisconsin, telephone (608) 266-2212. The information is available for MS-DOS computers as Lotus worksheets or R:BASE files. The advantage of the electronic format is that information can be readily updated and customized to individual users needs. It can also be easily sorted to answer a variety of questions. Contact the Lake Management Office for questions about current use.

Table A2. Sample summary sheet, *Potamogeton pectinatus*

SPECIES: *Potamogeton pectinatus*

SPECIES CODE: POTPE

COMMON NAME: sago pondweed

BASIC INFORMATION*

Life form: S Life cycle: P Status: A

Life form: E-emergent, S-submergent, FL-floating leaved, FF-free floating

Life cycle: A-annual, P-perennial, B-both

Status: A-abundant, C-common, I-infrequent, R-rare, EN-endangered,
N-non native

HABITAT PREFERENCE*

Substrate	Turbidity	Summer drawdown	Winter drawdown
0	Y	-	V

Substrate preference: S-soft, H-hard, O-no preference

Turbidity: Y-positive association with turbid water, N-negative
association, O-no significant association

Drawdown: I-increases with drawdown, D-decreases, V-variable response

WILDLIFE AND ENVIRONMENTAL VALUES*

Water-fowl food	Water-fowl value	Other bird food	Other bird cover	Musk-rat food	Substrate stabili-zation	Potential nuisance	Fish value
E	-	-	-	-	-	X	F,C

Part consumed: A-seeds, B-tubers, C-foliage and stems

Food value: E-excellent, G-good, F-fair, P-poor

Fish value: F-food or supports fish food fauna, C-cover, S-spawning habitat

PROPAGATION METHODS*

Transplants	Whole plants	Roots	Cuttings	Tubers	Winter buds	Seeds
X	-	X	X	X	-	X

HERBICIDE SUSCEPTIBILITY*

Endothall	Diquat	2-4,D	Glyphosate	Fluridone	Simazine
C	C	N	-	C	C

C-controlled, ?-questionable control results dependent on chemical
formulation or environmental conditions, N-not controlled
